#### ABSTRACT

This study presents the derivation of a diffuser design parameter, which takes into account losses due to the geometry of the diffuser.

A criterion for design of annular diffusers, using the design parameter to predict losses, is developed from reference data and model tests.

A curved wall annular diffuser was designed and tested to verify the predictions of the design criterion for an arbitrary diffuser.

#### **ACKNOWLEDGEMENT**

The author wishes to acknowledge the guidance given by Professor M. H. Vavra of the Department of Aeronautics of the Naval Postgraduate School, and assistance of Mr. James E. Hammer and the technical staff of the Turbopropulsion Laboratory in the preparation of the experimental portion of this thesis.

Special thanks go to Mr. Gordon Gulbranson, non-metal model maker of the Department of Aeronautics for the beautiful diffuser models which he fabricated.

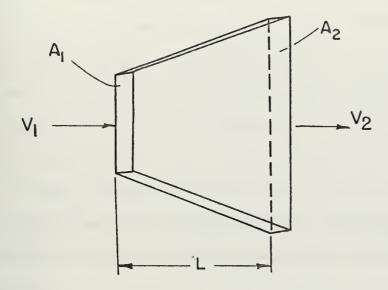

#### I. INTRODUCTION

In the design of annular diffusers, such as those found in jet engines, and turbomachines, there has been a problem defining parameters which indicate sufficiently the optimum design range for varying geometries. Many schemes have been devised, such as the so-called "equivalent conical angle method", to relate a diffuser to a known shape. The difficulty in these approaches has been that each person using the method developed a slightly different approach which resulted in a variety of descriptions for the same diffuser. Gleason [1] gives a summary of such methods and points out the difficulty in correlating data from different sources.

Some apparent problems arise when describing a diffuser by inlet area, exit area, length, difference in inlet radii, equivalent cone angle, or combinations of these parameters developed by empirical means. Although these terms give some intuitive feel for the way a diffuser would perform, two diffusers which differ widely in performance could have the same definition.

The simple example of Figure 1, where the two diffusers have the same inlet area, exit area, length and possibly the same divergence angle, makes it immediately obvious that the two diffusers would not have the same losses. The velocity and pressure distributions through the diffuser channel have a direct effect on the boundary layer development, which in turn controls the frictional losses. The widely differing geometries of the two above-mentioned diffusers would cause large differences in boundary layer growth. Therefore,

$$A_{1} = A_{1}^{1}$$
,  $A_{2}^{=} A_{2}^{1}$ ,  $L = L^{1}$ ,  $L/A_{1} = L^{1}/A^{1}$ ,  $V_{1} = V_{1}^{1}$   $V_{2} \neq V_{2}^{1}$ 

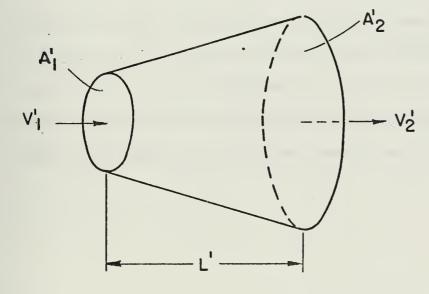

FIGURE 1

Example of diffusers which previously had the same description.

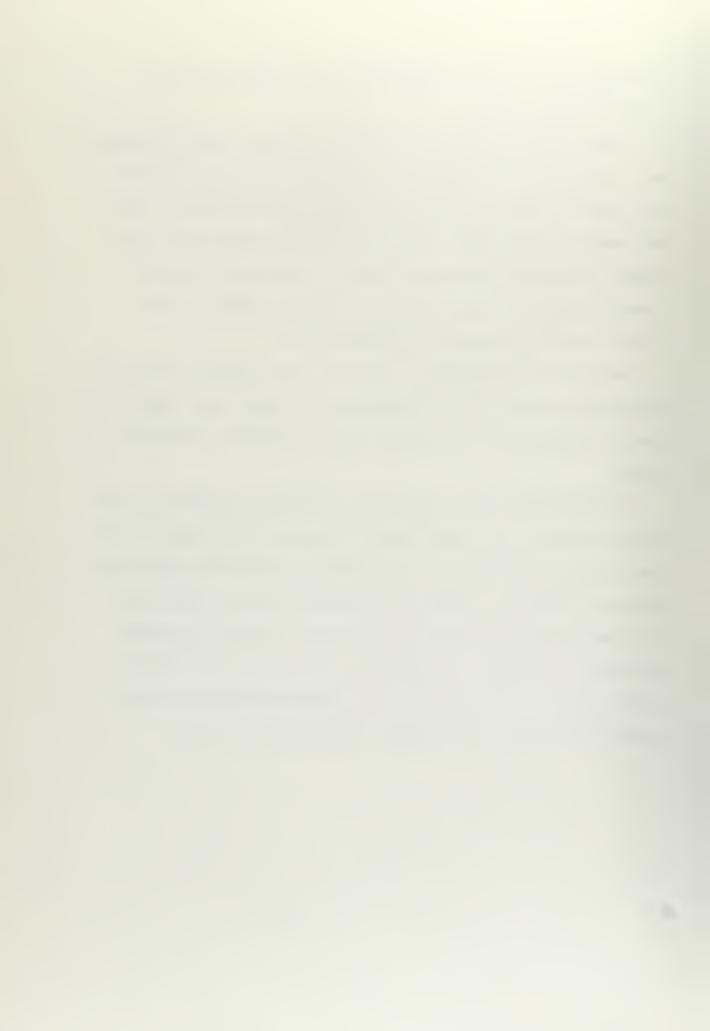

the performance of the two would differ and a similar description would not be appropriate.

Sovran and Klomp [2] have empirically developed a fairly successful set of parameters for straight wall annular diffusers. The geometric area ratio was taken as the primary factor affecting diffusion, and a non-dimensionalized length when combined with the area ratio, gave an overall criterion for the pressure-gradient affecting the boundary layer development. Their description of annular diffusers is at present limited to designs with straight walls.

Vavra [3 and 4] presented the idea of a shape factor or parameter which includes the effects of diffusion and boundary layer influence for the evaluation and preliminary design of diffusers of arbitrary shapes.

The objectives of this study were to present the derivation of the shape parameter,  $\Omega$ , to substantiate its usefulness from reference data, and to evaluate the validity of the results by construction and investigation of a family of straight wall diffusers such as those in Ref. 2. To show that the design shape parameter may be applied to diffusers other than those with straight walls, a curved wall diffuser such as might be found at the exit of the high pressure compressor of a jet engine was designed for an optimum  $\Omega$  and evaluated by tests.

### II. DEVELOPMENT OF THE SHAPE PARAMETER OMEGA $(\Omega)$

The function of a diffuser is to convert a portion of the kinetic energy of the free stream into static pressure by a compression process similar to that in a mechanical compressor. The shape parameter, Omega  $(\Omega)$ , to be used for diffuser design, can be evolved by examining the differential entropy changes of such a polytropic compression process.

#### A. ENTROPY CHANGE OF A ONE-DIMENSIONAL, FRICTIONAL FLOW

An expression for the differential entropy change of a polytropic compression may be found by investigating a one-dimensional flow in a diverging channel, such as shown in Fig. 2. A momentum balance on the differential volume of Fig. 2 gives

$$\dot{m}$$
 (V / dV) -  $\dot{m}$ V = pA - (p / dp) (A / dA) / (p / dp/2) dA -  $\tau$ CdL which reduces to (1)

$$\dot{m} dV = - Adp - \tau CdL$$
 (2)

or

$$dp = -\frac{\dot{m}}{A} dV - \frac{\tau C}{A} dL$$
 (3)

where the values of A, C, p, dL, V, and  $\tau$  are as defined in Fig. 2. Introducing the equation of continuity,

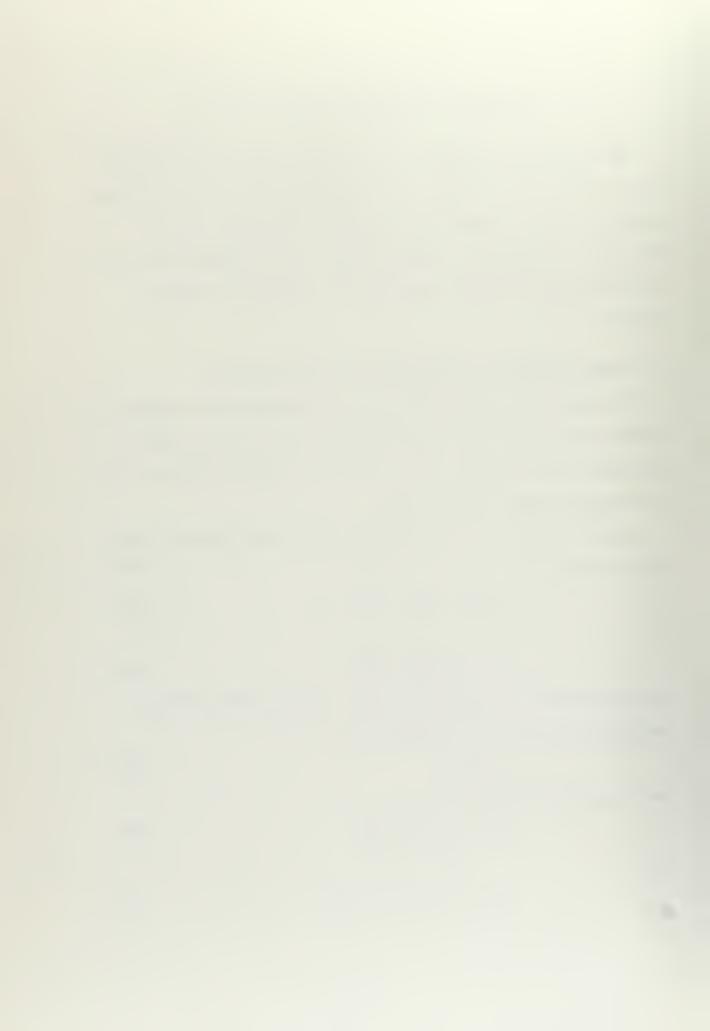

$$\dot{m} = \rho V A$$
 (4)

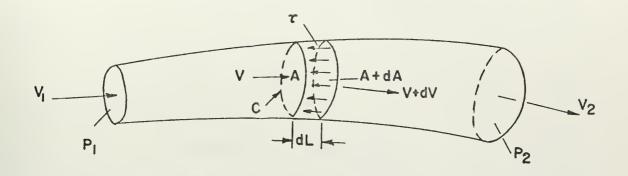

into equation (3) results in

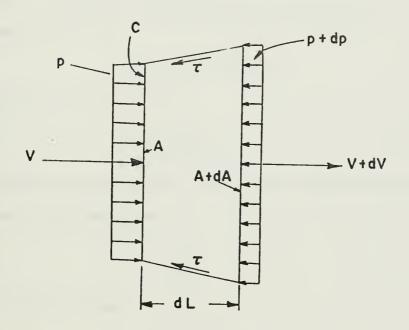

$$dp = - \rho V dV - \frac{\tau C dL}{A}$$
 (5)

or

$$\frac{\mathrm{d}p}{\rho} = -\mathrm{d}(V^2/2) - \frac{\tau}{\rho} \frac{\mathrm{C}}{\mathrm{A}} \mathrm{dL}$$
 (6)

A = Flow Cross - Sectional Area

C = Wetted Perimeter

p = Static Pressure

V = Average Veloc /

τ = Wall Shear Lineses L = Meridional Long

FIGURE 2

One-dimensional flow in a diverging channel.

with the First Law of Thermodynamics

$$dq = du \neq pdv = dh - vdp = dh - \frac{1}{\rho} dp = Tds$$
 (7)

or

$$\frac{dp}{\rho} = dh - Tds \tag{8}$$

Equating (6) and (7) gives

dh / 
$$d(V^2/2)$$
 - Tds =  $\frac{T}{\rho} \frac{C}{A} dL$  (9)

The first two terms of (9) combine to the derivative of the total enthalpy, H, and if the flow is restricted to an adiabatic case, with no energy in any form transferred between the fluid and its surroundings, the total enthalpy is constant and its derivative is equal to zero.

Therefore,

$$dH = d (h + v^2/2) = 0$$

and equation (8) simplifies to

$$Tds = \frac{\tau}{\rho} \frac{C}{A} dL \tag{10}$$

Introducing the concept of the local coefficient of skin friction in a one-dimensional flow,

$$c_{f} = \frac{\tau}{1/2\rho V^{2}} \tag{11}$$

equation (10) becomes

$$Tds = \frac{c_f}{2} V^2 \frac{C}{A} dL$$
 (12)

Introducing equation (4) and the equation of state for a perfect gas in (12) results in an expression for the differential entropy change,

$$ds = \frac{c_f}{2} \frac{\dot{m}^2}{\rho_A^{23}} \frac{C}{T} dL = \frac{c_f}{2} \frac{\dot{m}^2}{\rho} \frac{R_g}{\rho} \frac{C}{A^3} dL$$
 (13)

## B. ENTROPY CHANGE FROM THERMODYNAMIC CONSIDERATIONS

The differential change in entropy can also be found for an adiabatic, polytropic compression process as shown in the T-s diagram of Fig. 3. The definition of polytropic efficiency is,

$$\eta_{p} \equiv \frac{dT_{is}}{dT} \tag{14}$$

The isentropic relation for a differential compression from p to  $p+d\,p$  is

$$\frac{T + dT_{is}}{T} = \left(\frac{p + dp}{p}\right)^{\frac{\gamma - 1}{\gamma}}$$
(15)

By expanding (dp/p) by a binomial series, and assuming dp to be small compared to p,

$$dT_{is} \doteq T \frac{\gamma - 1}{\gamma} \frac{dp}{p} \tag{16}$$

Combining (14) and (16) gives

$$dT = \frac{T}{\eta_p} \frac{\gamma - 1}{\gamma} \frac{dp}{p}$$
 (17)

Solving equation (7) for

$$ds = c_{p} \frac{dT}{T} - \frac{1}{\rho T} dp$$

and introducing

$$c_p = R_g \frac{\gamma}{\gamma - 1}$$

and the perfect gas law

$$p/\rho = R_g T$$

results in an expression for

$$ds = R_g \left[ \frac{\gamma}{\gamma - 1} \frac{dT}{T} - \frac{dp}{p} \right]$$
 (18)

Substituting (17) into (18) gives

$$ds = R_g \frac{dp}{p} \left[ \frac{1}{\eta_p} - 1 \right]$$
 (19)

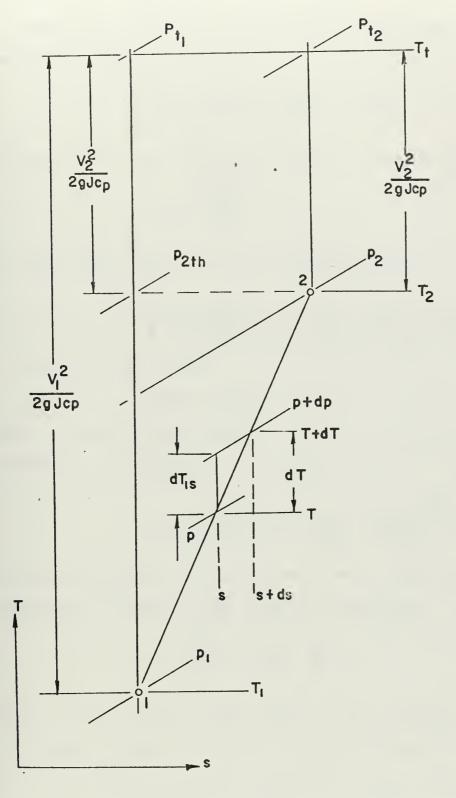

FIGURE 3

T--s diagram for an adiabatic, polytropic compression in a stationary duct.

## C. DEFINITION OF OMEGA $(\Omega)$

Equating the two values of differential entropy change from equations (13) and (19) results in

$$\frac{c}{2} \frac{\dot{m}}{\rho} \frac{c}{A^3} \frac{R_g}{p} dL = \frac{R_g}{p} \left[ \frac{1}{\eta_p} - 1 \right] dp$$
 (20)

Introducing the concept of referred flow rate, a dimensionless quantity,

$$\dot{\mathbf{m}}_{1r} \equiv \sqrt{\frac{R_g T_1}{p_1 A_1}} \quad \dot{\mathbf{m}} \tag{21}$$

and substituting (21) into (20) and rearranging gives

$$\frac{c_f}{2} \dot{m}_{1r}^2 \left(\frac{A_1}{A}\right)^3 \frac{C}{A_1} dL = \left[\frac{1}{\eta_p} - 1\right] \frac{\rho}{\rho_1} d\left(\frac{p}{\rho_1}\right)$$
 (22)

For a polytropic process

$$p/\rho^n = constant$$

where n is the polytropic exponent.

Rewriting (22) in the form

$$\frac{c_f}{2} \dot{m}_{1r} \left(\frac{A_1}{A}\right)^3 \frac{C}{A_1} dL = \left[\frac{1}{\eta_p} - 1\right] \left(\frac{p}{p_1}\right)^{1/n} d\left(\frac{p}{p_1}\right)$$
(23)

gives two independent differentials which can be integrated.

Defining the left side of (23) as  $dX_1$  and integrating,

$$X_{1} = \int_{0}^{\overline{L}} \frac{c_{f}}{2} \dot{m}_{1r}^{2} \left(\frac{A_{1}}{A}\right)^{3} \frac{C}{A_{1}} dL \qquad (24)$$

where  $\overline{L}$  is the meridional length along the mean streamline.

Assuming an average value of coefficient of friction,  $c_f$ , for the whole surface and that  $\dot{m}_{1r}$  is a constant for a given flow rate, (24) may be rewritten as

$$X_{1} = \frac{\bar{c}_{f}}{2} \dot{m}_{1r}^{2} \int_{0}^{\bar{L}} (A_{1})^{3} \frac{C}{A_{1}} dL$$
 (25)

The integral of (25) is a parameter which contains the flow area ratio, the diffuser length, and the wetted surface, and will be called the "diffuser shape parameter", defined by

$$\Omega = \int_{0}^{L} \left(\frac{A_{1}}{A}\right)^{3} \frac{c}{A_{1}} dL$$
 (26)

# D. RELATIONS BETWEEN Ω AND DIFFUSER PERFORMANCE

Defining the right-side of (23) as  $dX_2$ ,

$$X_{2} = \int_{1}^{p_{2}/p_{1}} \left[ \frac{1}{\eta_{p}} - 1 \right] \left( \frac{p}{p_{1}} \right)^{1/n} d \left( \frac{p}{p_{1}} \right)$$
 (27)

If  $\eta_{\mbox{\scriptsize p}}$  and n are assumed constant,

$$X_{2} = \left[\frac{1}{\eta_{p}} - 1\right] \frac{1}{(1/n + 1)} \left[\left(\frac{p_{2}}{p_{1}}\right)^{(1/n + 1)} - 1\right]$$
 (28)

For

$$p_2 = p_1 + \Delta p$$

the binominal expansion

$$\left(\frac{p_2}{p_1}\right)^{1/n+1} = \left(\frac{p_1 + \Delta_p}{p_1}\right)^{1/n+1} = \left(1 + \frac{\Delta_p}{p_1}\right)^{1/n+1}$$

$$= 1 + \left(\frac{1}{n} + 1\right) \frac{\Delta_p}{p_1} + \cdots$$

Assuming  $\Delta p$  is much less than  $p_1$  and omitting higher order terms from the binomial expansion, equation (28) becomes

$$X_2 = \left[\frac{1}{\eta_p} - 1\right] \frac{\Delta p}{p_1} \tag{29}$$

Equating  $X_1$  and  $X_2$ ,

$$\left[\frac{1}{\eta_{p}} - 1\right] \frac{\Delta p}{p_{1}} = \frac{c}{2} \dot{m}_{1r}^{2} \Omega \tag{30}$$

With the equation of continuity, equation (21) becomes

$$\dot{m}_{1r} = \rho_1 V_1 A_1 \frac{\sqrt{\frac{R_g T}{g}}}{\rho_1 A_1}$$
 (31)

Substituting  $\dot{m}_{1r}$  into equation (30)

$$\left[\frac{1}{\eta_{p}} - 1\right] \frac{\Delta_{p}}{1/2\rho_{1}V_{1}^{2}} = \overline{c}_{f} \Omega$$
 (32)

For a constant total temperature, equation (18) becomes

$$ds = - R_g \frac{dP_t}{P_t}$$

Thus equation (19) becomes

$$-\frac{\mathrm{d}P_{t}}{P_{t}} = \left[\frac{1}{\eta_{p}} - 1\right] \frac{\mathrm{d}p}{p} \tag{33}$$

Integrating (33)

$$\ln \left(\frac{\mathbf{P}_{t_1}}{\mathbf{P}_{t_2}}\right) = \left[\frac{1}{\eta_p} - 1\right] \ln \left(\frac{\mathbf{P}_2}{\mathbf{P}_1}\right) \tag{34}$$

Using the assumption that  $P_{t_2} = P_{t_1} + \Delta P_t$  and  $P_2 = P_1 + \Delta P_t$ , where  $\Delta P_t$  and  $\Delta P_t$  are small compared to  $P_t$  and  $P_t$  and  $P_t$  are spectively, and with the truncated power series expansion of  $P_t$  and  $P_t$  are  $P_t$  are  $P_t$  are  $P_t$  and  $P_t$  are  $P_t$  a

$$\frac{\Delta P_t}{P_{t_1}} = \left[\frac{1}{\eta_p} - 1\right] \frac{\Delta p}{P_1}$$

or

$$\left[\frac{1}{\eta_{p}} - 1\right] \Delta_{p} = \Delta P_{t} \left(\frac{P_{1}}{P_{t1}}\right) = \Delta P_{t} \frac{1}{1 + \frac{\gamma}{2} M_{1}^{2}}$$
(35)

Since for an incompressible flow,  $M^2$ , is small compared to unity,

$$\left[\frac{1}{\eta_{p}} - 1\right] \Delta_{p} = \Delta P_{t} \tag{36}$$

Substituting (36) into (32) gives

$$\overline{c}_{f} \Omega = \frac{\Delta P_{t}}{1/2 \rho_{1} V_{1}^{2}}$$
(37)

In Ref. 2, the Pressure Recovery Coefficient is defined as the ratio of the actual pressure rise and the maximum attainable one for the particular flow rate, or

$$c_{pr} = \frac{p_2^{-p_1}}{1/2 \rho_1 v_1^2}$$
 (38)

Defining the Ideal Pressure Recovery Coefficient as that which would result for an isentropic compression producing the theoretical pressure  $p_2$  of Fig. 3,

$$c_{pri} = \frac{P_{2_{th}}^{-p_1}}{1/2 \rho_1 V_1^2}$$
 (39)

For isentropic flow  $\Delta P_t$  = 0, and assuming density to be constant and introducing the equation of continuity,

$$c_{pri} = \frac{\rho/2 \ v_1^2 - \rho/2 \ v_2^2}{\rho/2 \ v_1^2} = 1 - \left(\frac{A_1}{A_2}\right)^2$$
 (40)

From equation (40),

$$\rho/2 \, v_2^2 = \rho/2 \, v_1^2 \, [1 - C_{pri}]$$

Then

$$P_{t_1} - P_{t_2} = P_1 + \rho/2 V_1^2 - P_2 - \rho/2 V_1^2 [1-C_{pri}]$$

or

$$\frac{P_{t_1} - P_{t_2}}{\rho/2 V_1^2} = \frac{P_1 - P_2}{\rho/2 V_1^2} + C_{\text{pri}}$$
(41)

Using the definition of  $C_{pr}$ , (38), and equation (37) there is

$$\overline{\Omega_{c}}_{f} = C_{pri} - C_{pr}$$
(42)

or

$$\overline{c}_{f} = \frac{c_{pri} - c_{pr}}{\Omega} \tag{43}$$

Hence, after having previously determined  $\Omega$ , the average frictional loss coefficient,  $\bar{c}_f$ , can be calculated from the measured quantities  $p_1$ ,  $q_1$ ,  $A_1$ ,  $p_2$ , and  $A_2$ .

# III. TEST INSTALIATION AND INSTRUMENTATION

The apparatus used in this investigation was located in Building

230 at the Turbopropulsion Laboratories of the Department of Aeronautics,

Naval Postgraduate School, Monterey, California.

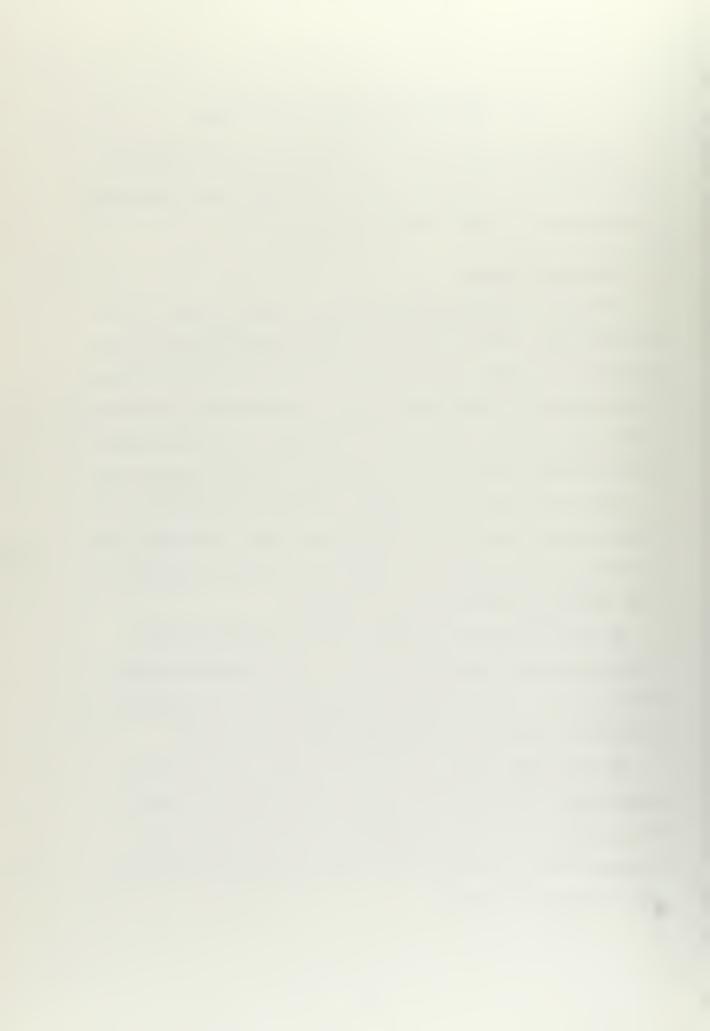

#### A. AIR DELIVERY SYSTEM

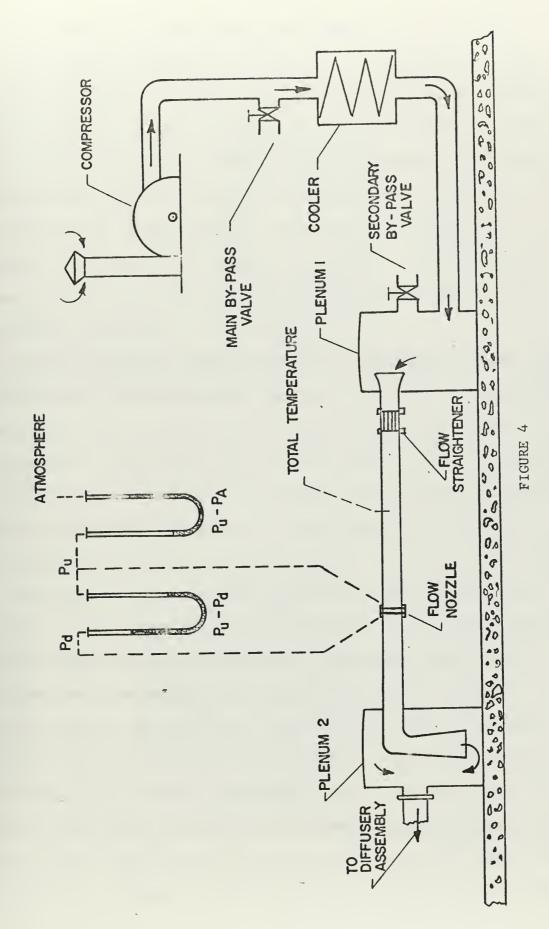

A schematic drawing of the installation is shown in Fig. 4. The air source was a 200 H.P., Carrier centrifugal compressor with a maximum flow rate of about four pounds mass of air per second at a pressure ratio of about two. Gross throttling was accomplished by a main by-pass valve ahead of the air coolers. Fine adjustments of the flow rate were made by bleeding air from plenum (1) through a secondary by-pass valve.

The air from plenum (1) discharged through a flow straightener into a four inch pipe containing a flow measuring nozzle. The nozzle used was the same as that described by Kelly [5], which had a diameter of 3.022 inches and a diameter ratio,  $\beta$ , of 0.734.

The flow was diffused into plenum (2) by a ten degree conical diffuser extending downward from the inlet. The discharge of plenum (2) was into a rectangular wooden duct containing flow straighteners and a total temperature, iron-constantan thermocouple probe.

The mean stream velocity in the duct at maximum flow rate was approximately 20 to 25 feet per second. Transition pieces shown in Fig. 5 were used to change the geometry of the flow channel from rectangular to circular and to accelerate the flow to the diffuser inlet velocity and pressure.

Schematic of the air delivery system.

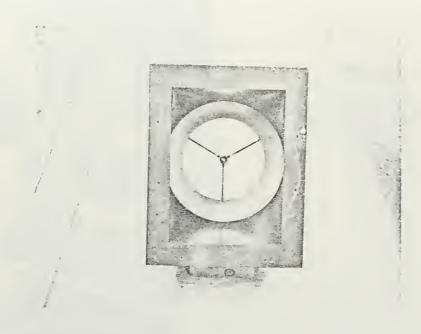

#### B. DESCRIPTION OF DIFFUSER MODELS AND ASSEMBLY

The diffuser assemblies of the two models constructed and their supporting assembly are shown in the photographs of Figures 6 through 10. The supporting assembly consisted of the duct transition pieces with a cylindrical portion, shown in Fig. 6, containing three equally spaced support struts for a cantilevered center-body, so that no obstructions or supports would be necessary in the diffuser flow channel. The flow was accelerated to the diffuser entrance in an annular space created by the nose of the center-body assembly and a converging outer wall.

A straight section, where the annular area remained constant, was provided just downstream of the inlet to provide room for flow measurements and surveys, as shown in the schematic of Fig. 11. Smooth transitions to the diffuser contour were arranged as shown in Figures 8 and 9. All computations of the diffuser shape parameter included the flow area from the inlet plane to the exit plane of the diffuser, inclusive of the cylindrical inlet section.

The diffuser inlet plane was provided with three supports for probes, equally spaced around the outer periphery and bisecting the angles formed by the supporting struts of the center-body. These supports could accommodate both hot-wire and pressure probes for radial surveys. One support was used for a Kiel probe for the measuring of total pressure at the inlet plane. Three static pressure taps were provided in the same plane, 120 degrees apart on the outer wall. Three sets of static taps were placed axially downstream from the inlet static taps, at two-inch intervals on the outer wall of the first model, and on both the inner and outer walls at one-inch intervals on the second

model. Static pressure readings were found to be equal at all three stations around the circumference, and the three taps at each axial location were therefore connected together.

Model (1) had straight walls as illustrated in Fig. 12, with a wall divergence angle of 15 degrees for both the inner and outer contours. The construction was such that a series of four diffusers with different shape parameters could be produced by simply cutting off the end of the model. Model (2) had a more complicated shape, and was designed as described in Appendix B to show the validity of the  $\Omega$  parameter for curved-wall diffusers. A summary of the geometrical characteristics of both models is given in Table I.

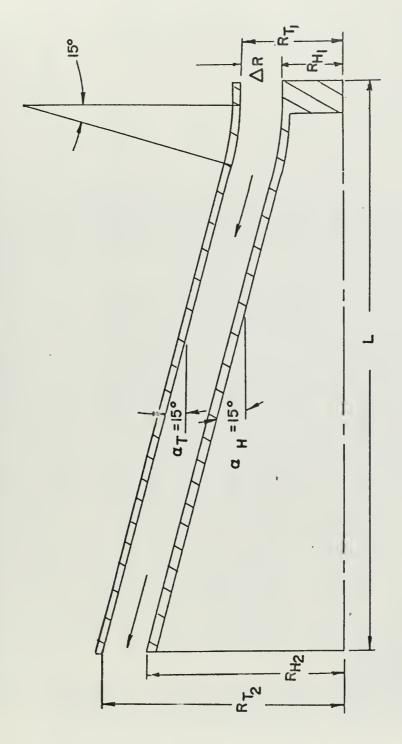

## C. INSTRUMENTATION

Pressure readings for the flow nozzle and the diffuser inlet were made with a Texas Instrument Fused Quartz Pressure Gage, which is shown in the overall view of the experimental apparatus of Fig. 13.

A constant pressure source calibration of the Pressure Gage, to a Meriam Vernier Manometer filled with water, gave a constant value of 0.800 inches of water per count, with a reading accuracy of  $\pm$  0.001 counts. This result was identical to that of Beck [6].

Pressure readings for five-hole probe measurements were made on a 235 cm, eight tube water manometer bank, which can be read to an accuracy of  $\pm$  0.1 cm. Static pressure measurements along the diffuser length were made on a 92 inch, 20 tube water manometer board with a reading accuracy of  $\pm$  0.05 inch. All pressure taps were connected to their respective reading devices with plastic tubing. A standard mercury wall-barometer was used for atmospheric pressure readings.

Schematic of diffuser Model (1) FIGURE 12

See Fig. 12 for description of dimensions.

See Section II for definition of  $\Omega$ 

FIGURE 13

Overall view of the experimental apparatus.

Temperature readings from the thermocouples upstream of the flow nozzle, and in the wooden duct, were obtained with a Leeds and Northrup portable potentiometer with compensated cold-junction, giving a reading accuracy of  $\pm$  0.01 mV. Adiabatic flow was assumed from the area of temperature measurement to that of pressure measurement.

Hot-wire measurements were conducted with a two channel, constant temperature, hot-wire anomometer manufactured by Applied Science, Carmel, California. The wires were 0.00015 inch diameter tungsten with a 0.1 inch gap. Surveys were taken radially from the outer to the inner wall.

### IV. EXPERIMENTAL PROCEDURES AND COMPUTATIONS

All reduction of data was carried out by the Fortran IV computer program "Omega" described in Appendix C.

#### A. PRESSURE

Pressures obtained from the Texas Instrument Fused Quartz Pressure

Gage were reduced to pounds per square inch by

$$p = 0.03613 \text{ K } p_{TT}$$
 (44)

where K = 0.8, the conversion factor from counts to inches of water,  $p_{\rm TI}$  is the pressure read in counts on the Pressure Gage, and the constant value, 0.03613, is the conversion factor for inches of water to pounds per square inch from Ref. 7.

Barometric pressure was converted from inches of mercury to pounds per square inch by equation (3-2) of Ref. 6.

$$p_{A} = 0.4912 \text{ p.} \left[ 1 - \frac{0.0001634 \text{ t}_{c}}{1 + 0.0001818 \text{ t}_{c}} \right]$$
 (45)

where the coefficients of  $t_c$ , the room temperature in degrees centigrade, are the thermal expansion coefficients of mercury and brass. The factor 0.4912 is the conversion factor for inches of mercury at  $0^{\circ}$ C to pounds per square inch from Ref. 7.

# B. TEMPERATURE

Thermocouple readings, recorded in millivolts, were converted to degrees Fahrenheit by the temperature relationship,

$$t_f = 32.144 \text{ } f 35.77 \text{ mV} - 0.4518 \text{ mV}$$
 (46)

obtained from a least squares fit of data from Ref. 8. This relation holds for temperatures below 100 degrees Fahrenheit, with the cold-junction maintained at 32 degrees, or compensated to 32 degrees by the standard cell of the Leeds and Northrup measuring apparatus.

#### C. FLOW RATE

After setting the desired flow rate, the fluid temperatures were allowed to stabilize before data were taken. Upstream static pressure,  $p_u$ , differential pressure across the flow nozzle,  $(p_u-p_d)$ , and the upstream total temperature,  $t_{fu}$ , are necessary to compute flow rate as described in Appendix A of Ref. 5.

$$\dot{w} = \dot{w} \sqrt{\frac{p_u}{t_{fu}}} \sqrt{\frac{g_c}{R_g}}$$
 (47)

and

$$\dot{\mathbf{w}} = 11.30 \ \varepsilon \ \mathbf{f_t} \sqrt{\frac{\mathbf{p_u} - \mathbf{p_d}}{\mathbf{p_u}}} \tag{48}$$

where  $\overset{*}{w}$  is the equivalent flow rate, which has dimension in  $^2$ .

The so-called expansion coefficient,  $\epsilon$ , is

$$\varepsilon = \sqrt{2.433 \frac{(1-x)^{1.428}}{x}} \left[ \frac{1 - (1-x)^{0.286}}{1 - .305(1-x)^{1.428}} \right]$$
 (49)

where

$$x = \frac{P_u - P_d}{P_u} \tag{50}$$

and

$$f_t = 1 \neq 0.0015 \left( \frac{t_{fu} - 60}{100} \right)$$
 (51)

is a correction factor that takes account of the thermal expansion of the nozzle throat diameter.

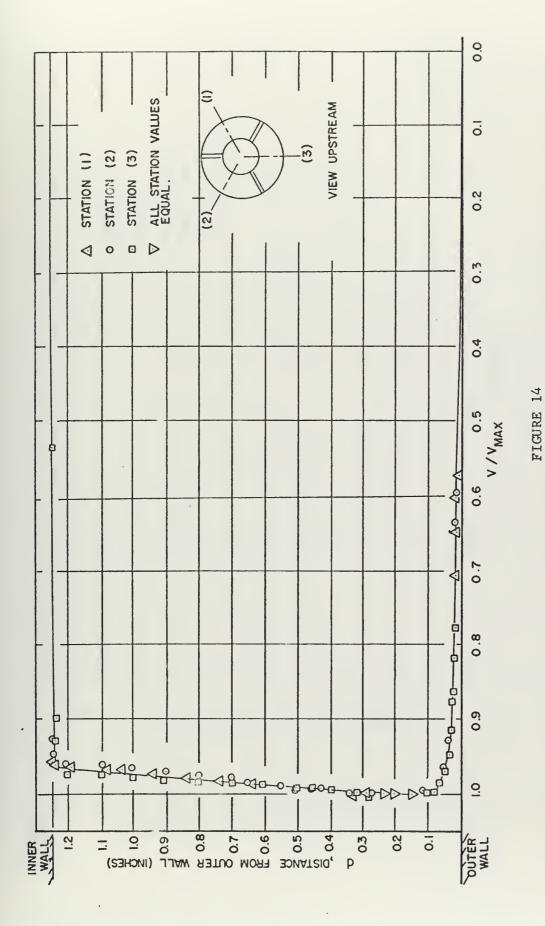

#### D. CHECK OF NOZZLE FLOW RATE WITH SURVEY DATA

Preliminary surveys at the inlet plane with a hot-wire probe indicated that the velocity profiles at the three stations surveyed were similar. Figure 14 is a least-squares fit of the data points from all three survey stations. The data were taken at varying flow rates at each station, and the velocities were found to vary within ± 1 per cent of the mean obtained with the least-square fit. Hence, the flow was very nearly axisymmetric, and the non-dimensional profiles remained unchanged at the different flow rates investigated. The boundary layer was very thin at the inlet. The actual thicknesses were 0.025 inch on the inner wall and 0.75 inch on the outer wall according to the measurements.

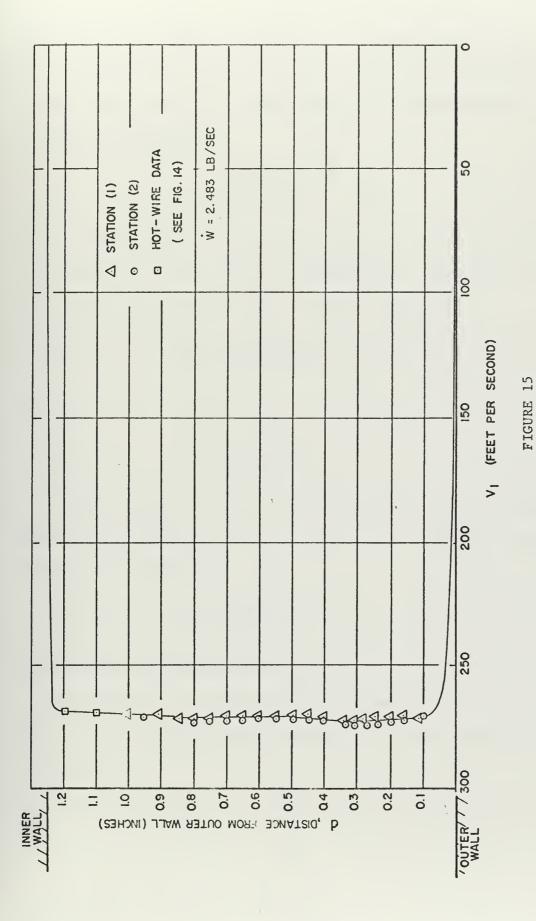

To verify the pressure and temperature measurements, a comparison was made of the flow obtained from the survey data at the inlet and that measured by the flow nozzle. A survey with a five-hole probe was made at the inlet plane to obtain the actual values of the velocities which are plotted in Fig. 15. Data for the five-hole probe were corrected by use of the calibration curves supplied by the manufacturer, United Sensor and Control Corporation. The velocity profile obtained was essentially the same as that of the hot-wire surveys. The hot-wire values were used for the boundary layer regions, where the immersion corrections for the pressure probe were unreliable. The yaw angles of the flow were less than  $\pm 1/2^{\circ}$ , and the flow had pitch angles between three and six degrees, with the velocities pointing outward from the center. The greatest velocities occurred at the outer wall.

Diffuser inlet plane, velocity survey in radial direction (measured by hot-wire anemometer).

Diffuser inlet plane, velocity survey in radial direction (measured by five-hold pressure probe).

The five-hole probe survey showed the total pressures and the velocities to be within two per cent of the mean values in the turbulent central region outside the boundary layers. An average Mach number of the flow in this central region was determined from the isentropic relationship

$$M_{1} = \left\{ \frac{2}{\gamma - 1} \left[ \left( \frac{P_{t} 1}{P_{1}} \right)^{\gamma} - 1 \right] \right\}$$
 (52)

The average static temperature at the inlet was determined by assuming adiabatic flow from the upstream total temperature probe to the inlet plane, which gave the isentropic relationship

$$\frac{T_{t1}}{T_1} = 1 + \frac{\gamma - 1}{2} M_1^2 \tag{53}$$

Hence,

$$T_1 = \frac{T_{t1}}{1 + \frac{\gamma - 1}{2} M_1^2} \tag{54}$$

Static pressure was found to be nearly uniform across the inlet plane, so that density was almost constant at this station. From the perfect gas relationship,

$$\rho_1 = \frac{P_1^{(144)}}{R_g g_c T_1} \tag{55}$$

with the units of slugs per cubic foot.

From the survey, the velocities were known as a function of radius, V(r). Thus, a flow rate was calculated at the inlet plane by numerical integration of

$$\dot{w}_1 = 2 \pi \rho_1 \int_{R_{H1}}^{R_{T1}} V(r) r dr$$
 (56)

assuming axisymmetric flow and no blockage from support strut wakes.

This flow rate was found to be three to four per cent higher than the flow rate obtained from the flow nozzle measurements. This comparison was considered satisfactory for the range of measuring capability.

### E. REYNOLDS NUMBER

The characteristic length for the Reynolds number (Re) was taken . as the hydraulic radius of the inlet annulus,  $\Delta R_1$ , as in Ref. 2, or

$$\Delta R_1 = \frac{2 \text{ (flow area)}_1}{\text{(wetted perimeter)}_1}$$
 (57)

Therefore,

$$Re = \frac{\rho_1 V_1 \Delta R_1}{\mu}$$
 (58)

and, substituting

$$\dot{\mathbf{w}} = \rho_1 \ \mathbf{V}_1 \ \mathbf{A}_1 = \rho_1 \ \mathbf{V}_1 \ \pi \ (\mathbf{R}_{\mathbf{T}_1}^2 - \mathbf{R}_{\mathbf{H}_1}^2) \tag{59}$$

the Reynolds number (Re) can be expressed in dimensionally correct units as

$$Re = \frac{\dot{w} (12)}{g \mu \pi (R_{T_1} + R_{H_1})}$$
 (60)

where viscosity,  $\mu$ , has a representative value of 3.9 x  $10^{-7}$   $1b_f$ -sec/ft<sup>2</sup> for the operating range of 85 to 95 degrees Fahrenheit. The flow rate,  $\dot{\mathbf{w}}$ , is in  $1b_m$ /sec, and the radii are expressed in inches.

# V. ANALYSIS OF TEST DATA FROM REFERENCE 2

Sovran and Klomp [2] made a study of more than one hundred annular diffuser configurations, and their published data was of a form suitable to be analyzed for the present purpose. Of the many other works published, none furnished a sufficiently wide cross-section of data which could be readily applied. Data from Ref. 2 were reduced by the Fortran IV program shown in Table D1. The results are listed in Table D2 and plotted on Fig. 16 for a Reynolds number of approximately 6 x  $10^5$ . Each set of data points represents a family of straight wall diffusers having the same inlet area and wall divergence angles as shown in Fig. 16. The data points fall within a band on the plot of  $\Omega$  c, versus  $\Omega$ , which is bounded by lines representing a dimensionless length description of the diffuser, L/AR. An investigation of the values of  $\overline{L}/\Delta R$  for existing diffuser designs indicates that the boundaries shown on Fig. 16 are in the range of practical designs. The points falling below  $L/\Delta R = 1.5$  represent designs which become so short that diffusion is degraded, and those above  $L/\Delta R = 13$  become excessively long for practical use. It can be seen, that as  $\Omega$  falls below approximately five, there is an abrupt rise in the value of  $\Omega c_f$ , which is representative of the entropy rise and thus of an increase of the losses in the diffuser. The trend of the curve for larger values of  $\Omega$  was found by considering that, as a diffuser with small divergence angles becomes long, its characteristics approach that of a pipe. Reference 9 gives the value of the coefficient of friction for an annular pipe as  $c_f = 0.01$  at Re = 6 x  $10^5$ . A pipe with  $L/\Delta R = 13$  has a value of

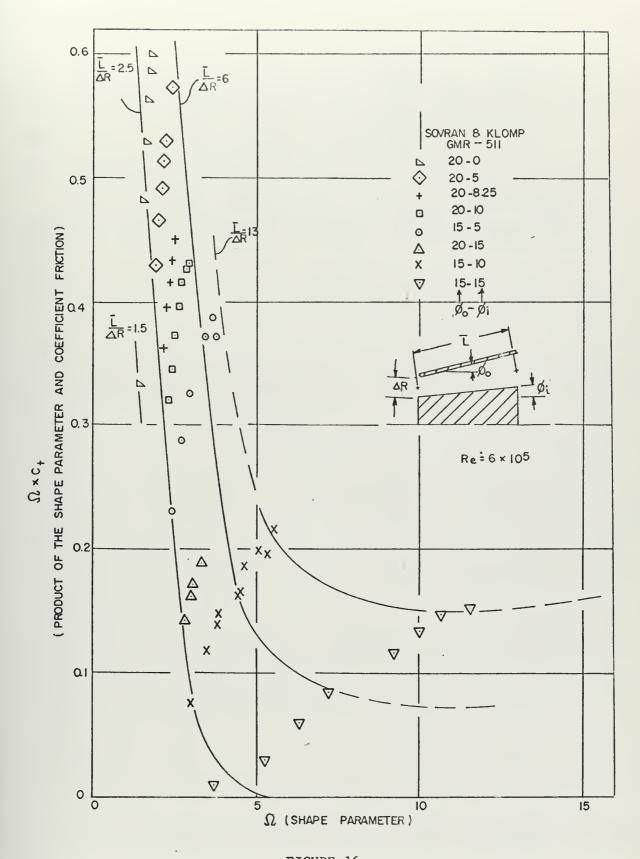

FIGURE 16  $\Omega \stackrel{-}{c_f} \mbox{ vs. } \Omega \mbox{ for Reference 2 data}.$ 

 $\Omega$  = 26 and  $\Omega$   $\overline{c}_f$  = 0.26, which is a higher value of  $\Omega$   $\overline{c}_f$  than that occurring from diffuser tests at  $\Omega$  = 11.5 and  $\overline{L}/\Delta R$  = 13, suggesting an upward trend in the curve for high values of  $\Omega$ . This trend indicates that a minimum of  $\Omega$   $\overline{c}_f$  occurs between about  $\Omega$  = 5 and  $\Omega$  = 15, possibly at a value of  $\Omega$  = 10, for an  $\overline{L}/\Delta R$  = 13.

Vavra [3] calculated values of  $\Omega$   $\overline{c}_f$ , for two-dimensional subsonic diffusers, which lie within the same band as the data plotted on Fig. 16.

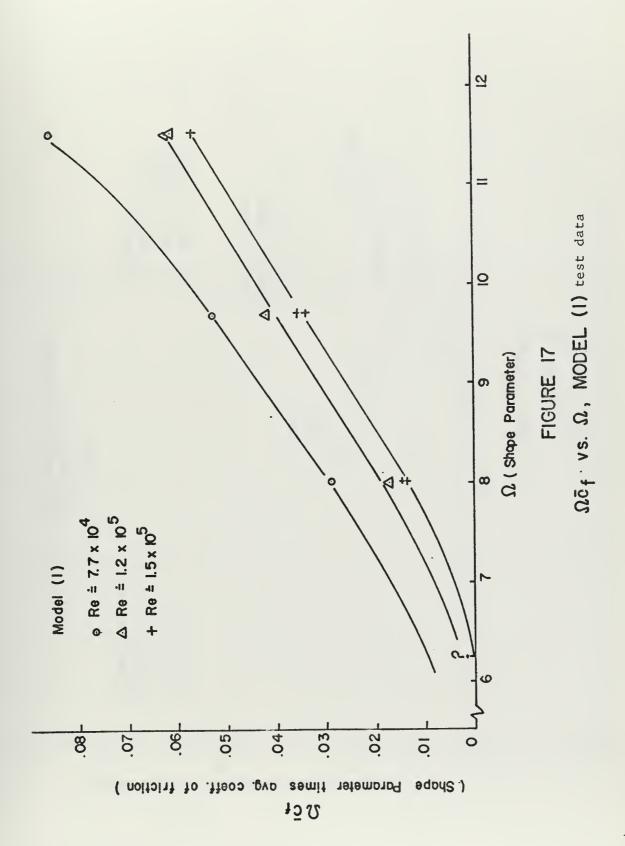

# VI. DISCUSSION OF TEST DATA

The test results obtained from diffuser Model (1) and Model (2) are given in Table II. The quantities  $\Omega$   $\overline{c}_f$  for Model (1) are plotted on Fig. 17 versus  $\Omega$ . Tests were made at different flow rates to investigate the effect of Reynolds number on the location of points in the  $\Omega$   $\overline{c}_f$  vs.  $\Omega$  plot for the different configurations of Model (1). Figure 17 shows that as Reynolds number increases the quantity  $\Omega$   $\overline{c}_f$  decreases, and vice versa. This effect could be anticipated from the trend of  $\overline{c}_f$  against Re for flows in annular pipes, as shown in Ref. 9.

The curve for  $L/\Delta R = 6$  and the curve for the family of diffusers with  $\Phi_0 = \Phi_1 = 15^\circ$ , from Fig. 16, and the curves from Fig. 17 were transposed to Fig. 18. The shape of the curves from data of Model (1) approximates that of the similar family of diffusers from Fig. 16 for  $\Phi_0 = \Phi_1 = 15^\circ$ . However, the values obtained from the tests of Model (1) are considerably lower than those from Ref. 2. This discrepancy may be explained by the fact that the models of Ref. 2 were constructed of wood and, therefore, had a higher wall roughness than the cast resin models used in this study. The value of  $c_f$  for a wood surface would be larger than that for a resin surface with lower wall roughness, similar to what can be seen from the Moody diagram for pipes of differing roughness.

The values of  $\Omega$   $c_f$  for configuration four of Model (1) became slightly negative. Values of  $\Omega$   $c_f$  from Ref. 2 data were also negative when  $c_{pr}$  became greater than  $c_{pri}$ . For an adiabatic process, the value  $\Omega$   $c_f$  cannot be negative, since  $c_{pr}$  is less than  $c_{pri}$  by definition. An investigation of the pressure measurements for configuration four of

Model (1) showed a fluctuation of the instrument readings of sufficient magnitude for  $C_{\rm pr}$  to be larger than  $C_{\rm pri}$ .

It can be anticipated that the curves of Fig. 16 will be shifted vertically up or down with Reynolds number similar to the condition in Fig. 17. The values of  $\Omega$  for the point of sharply increasing  $\Omega$   $\overline{c}_f$  would not be affected by a change in Re, since the entire band of data points would be displaced in the vertical direction only. To avoid large values of  $\Omega$   $\overline{c}_f$ , a minimum value of  $\Omega$   $\doteq$  5 should be used for most practical designs.

To demonstrate the usefulness of the design parameter  $\Omega$ , for complicated shapes, Model (2) was designed as outlined in Appendix B for a value of  $\Omega$  = 5.7, and  $\overline{L}/\Delta R$  = 6.85. Values of  $\Omega \doteq 6$  and  $\overline{L}/\Delta R \doteq 6$  were chosen for the original design point, to obtain an  $\Omega$   $\overline{c}_f \doteq 0.1$ .

By extrapolating from the curve for  $\overline{L}/\Delta R = 6$  of Fig. 16 to the data of Fig. 17 to show the effect of Re and the difference in the model surfaces, the heavy dashed curve of Fig. 18 was obtained. The data of Model (2), plotted on Fig. 18, verified the location of the  $\overline{L}/\Delta R$  curve for an arbitrary shaped diffuser.

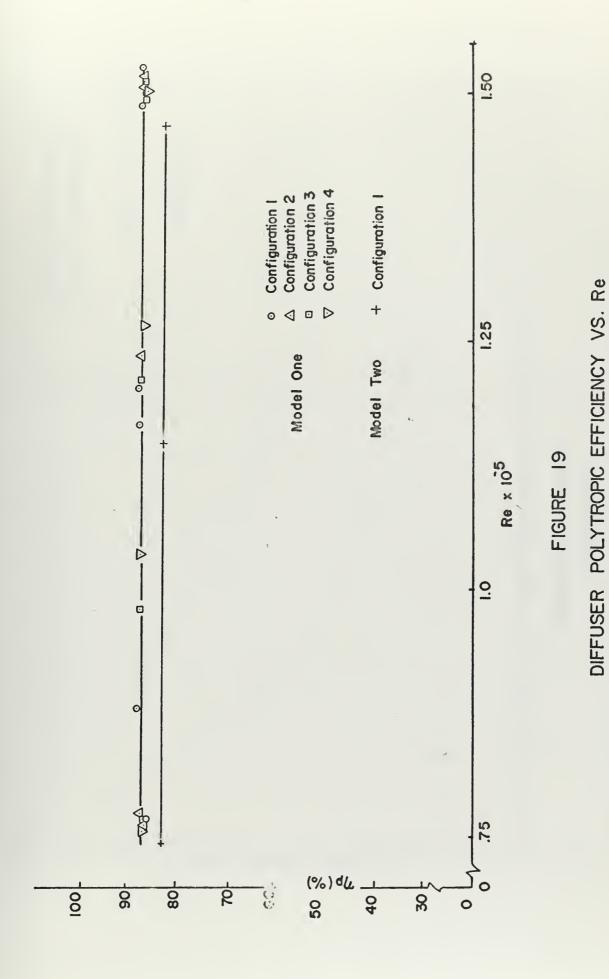

The efficiencies for both Model (1) and Model (2), plotted on Fig. 19, remained essentially constant through the Re range of this study.

Static pressure  $(p_w)$  on the inner and outer walls of Model (1) and Model (2) was non-dimensionalized by

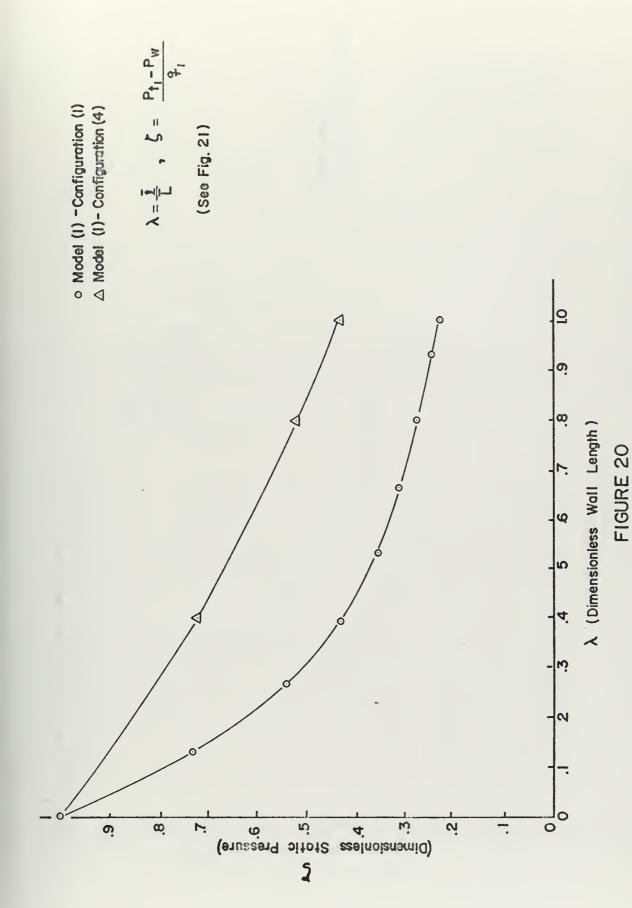

$$\zeta = \frac{P_{t1} - P_w}{q_1} \tag{61}$$

and plotted against non-dimensionalized, meridional wall length,  $\lambda = \overline{1/L}_W, \text{ on Figures 20 and 21, where } \overline{1} \text{ is the meridional distance}$  along the wall from the inlet to the pressure tap, and  $\overline{L}_W$  is the

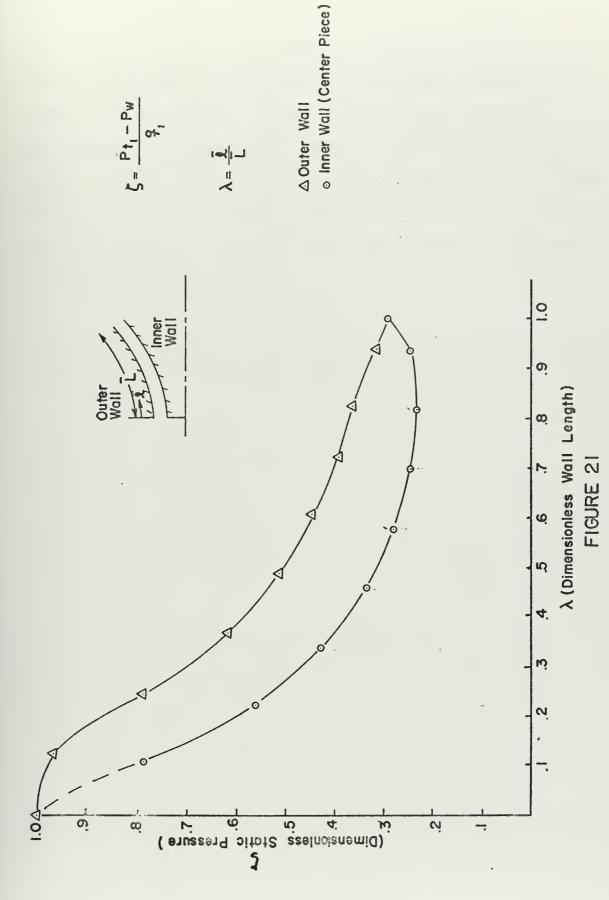

Dimensionless pressure distribution along outer wall of Model (1)

Dimensionless pressure distribution along the inner and outer walls of Model (2)

meridional wall length. Values for  $\zeta$ ,  $\lambda$ , and  $p_W$  are contained in Table III, for the outer wall of Model (1) and for both the inner and outer walls of Model (2). The static pressure became higher than the ambient pressure at about  $\lambda=0.5$  on the inner wall of Model (2), which gives a  $\zeta$  less than that at the exit. The value of  $\zeta$  reaches a minimum between  $\lambda=0.7$  and  $\lambda=0.9$  and increases again toward  $\zeta=0.293$  at the exit plane. This condition may be due to a separation of the flow, and indicates the need for proper wall contouring in addition to satisfying the criterion of  $\Omega$ .

# VII. CONCLUSIONS AND RECOMMENDATIONS

This paper presents a design parameter  $\Omega$ , for diffuser designs, which takes into account losses due to the geometry of the diffuser. It is shown from reference data and model tests that there is an abrupt increase in losses for diffusers designed for a value of  $\Omega$  less than about five, and that this effect is independent of Reynolds number.

The parameter  $\Omega$  is defined for incompressible, adiabatic flows. It is recommended that further experiments be made to extend the data for incompressible flows to higher values of  $\Omega$ , and that an investigation of the compressible case be made.

It is suggested that Model (2) be improved by recontouring the inner wall to avoid separation. It is recommended also that the present inner contour be cut off at the station where the value of  $\zeta$  is a minimum. Addition of static pressure taps on the inner wall at the inlet plane and a method for surveying the exit plane would provide data to better describe the flow.

It is recommended that the method of measuring pressure be investigated and improved to give more precise results for small, fluctuating pressure measurements, prior to conducting further tests on diffusers with  $\Omega$   $\overline{c}_f$  approaching zero.

#### APPENDIX A

#### DETERMINATION OF DIFFUSER EFFICIENCY

The diffuser efficiency was determined by the method of Vavra [10] for an adiabatic compression process with friction. The polytropic efficiency is defined for the differential compression from p to p  $\neq$   $\Delta p$  of Figure 3 as

$$\eta_{p} \equiv \frac{dT_{is}}{dT} \tag{A1}$$

The dimensionless flow function  $\Phi_{\mbox{\scriptsize c}}$  and the relation for the polytropic exponent, n, from Ref. 10 are

$$\Phi_{c} = \dot{w} \sqrt{\frac{R_{g}}{g_{c}}} \frac{1}{T_{1}} \frac{1}{P_{1}^{A_{2}}} = \sqrt{\frac{2\gamma}{\gamma-1}} \left[ \frac{T_{t}}{T_{1}} \left( \frac{P_{2}}{P_{1}} \right) - \left( \frac{P_{2}}{P_{1}} \right)^{n} \right]$$
(A2)

and

$$n = \frac{\gamma \eta_p}{1 - \gamma (1 - \eta_p)} \tag{A3}$$

where  $\dot{w}$ ,  $T_{t_1}$ ,  $T_1$ ,  $P_2$  and  $P_1$  are either measured or computed for the particular diffuser design.

For an incremental change in pressure from  $\mathbf{p}_1$  to  $\mathbf{p}_2$ , the pressure  $\mathbf{p}_2$  may be expressed as  $\mathbf{p}_1$  /  $\Delta \mathbf{p}$ , where  $\Delta \mathbf{p}$  is small with respect to  $\mathbf{p}_1$ . The pressure ratios in (A2) can be expressed as

$$\frac{P_2}{P_1} = \left(1 + \frac{\Delta_p}{P_1}\right) \tag{A4}$$

By the binominal expansion theorem,

$$\frac{2/n}{\left(\frac{p_2}{p_1}\right)} = \left(1 + \frac{\Delta p}{p_1}\right) = 1 + \frac{2}{n} \frac{\Delta p}{p_1} + \cdots$$
 (A5)

and similarly

$$\left(\frac{p_2}{p_1}\right)^{\frac{n+1}{n}} = 1 + \frac{n+1}{n} \frac{\Delta p}{p_1} + \cdots$$
 (A6)

and by assuming  $\Delta p$  to be small, the  $(\Delta p/p_1)^2$  and higher order terms are much smaller than  $\Delta p/p_1$  and are omitted.

From (A2)

$$\Phi_{c}^{2} \frac{\gamma - 1}{2\gamma} = \frac{T_{t_{1}}}{T_{1}} \left(\frac{P_{2}}{P_{1}}\right)^{2/n} - \left(\frac{P_{2}}{P_{1}}\right)^{\frac{n+1}{n}}$$
(A7)

Substituting expressions (A5) and (A6), and solving for n, gives

$$n = \frac{\frac{\Delta p}{p_1} \left[ 2 \frac{T_{t_1}}{T_1} - 1 \right]}{\frac{\gamma - 1}{2\gamma} \frac{\Phi^2_c}{C} - \frac{T_{t_1}}{T_1} + 1 + \frac{\Delta p}{p_1}}$$
(A8)

Equating (A3) and (A8) gives

$$\eta_{p} = \frac{\frac{\Delta p}{p_{1}} \left[ 2 \frac{T_{t_{1}}}{T_{1}} - 1 \right]}{\frac{\gamma}{\gamma - 1} \left( \frac{t_{1}}{T_{1}} - 1 \right) \left( 2 \frac{\Delta p}{p_{1}} + 1 \right) - \frac{\Phi^{2}}{2}}$$
(A9)

with

$$\frac{T_{t_1}}{T_1} = 1 + \frac{\gamma - 1}{2} M_1^2 \tag{A10}$$

the polytropic efficiency is

$$\eta_{p} = \frac{2 \frac{\Delta p}{p_{1}} \left[ 1 + (\gamma - 1) M_{1}^{2} \right]}{\Phi_{c}^{2} - \gamma M_{1}^{2} \left[ 2 \frac{\Delta p}{p_{1}} + 1 \right]}$$
(A11)

# APPENDIX B

## DESIGN OF DIFFUSER MODEL (2)

From the results of Ref. 2 and the test data of Model (1), a design point of  $\Omega \doteq 6$  and  $L/\Delta R \doteq 6$  was chosen from Fig. 18 for Model (2). The inlet area of Model (2) was the same as for Model (1).

From equation (42) of the main text,

$$C_{pri} - C_{pr} = \Omega \overline{c}_{f}$$

or, from equation (40), and a value of  $\Omega \overline{c}_f = 0.1$ ,

$$\left[1 - \left(\frac{A_1}{A_2}\right)^2\right] = 0.1 + C_{pr}$$
 (B1)

For the range of C pr from 0.65 to 0.72 for a  $\overline{L}/\Delta R \doteq$  6, equation (B1) gives

$$A_2 = \frac{A_1}{1 - (0.1 + C_{pr})}$$
 (B2)

giving a range of  $A_2$  from 39 to 51 in<sup>2</sup>.

An approximate radius was chosen to give a reasonable axial opening at a radial exit plane for  $A_2 \doteq 45 \text{ in}^2$ .

Since the outer surface, E, of Fig. 22 was most critical from the standpoint of flow separation, it was designed first. A smooth curve of the desired shape was sketched in for surface E. To approximate the curve sketched, a series of circular arcs were constructed which provide for simple tooling layouts.

Figure 23 shows the method by which two circular arcs are fitted to satisfy the condition that both have centers on the same line at their tangent point (4), and that they fit into a given length, L.

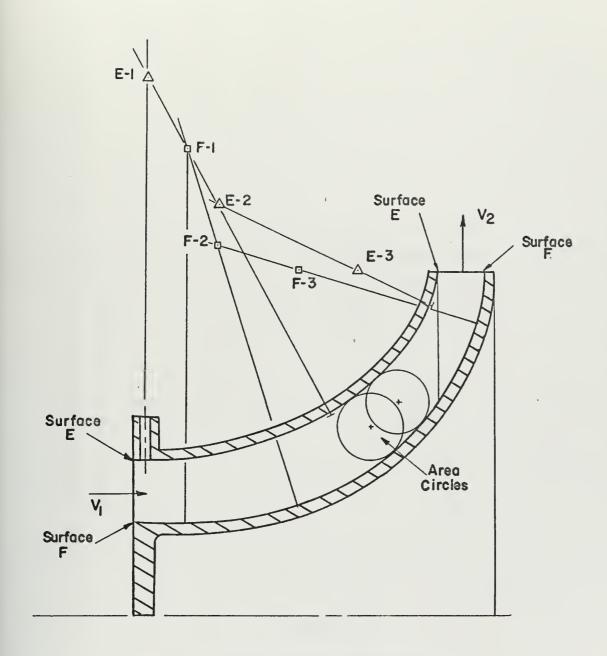

FIGURE 22
Design of Model (2)

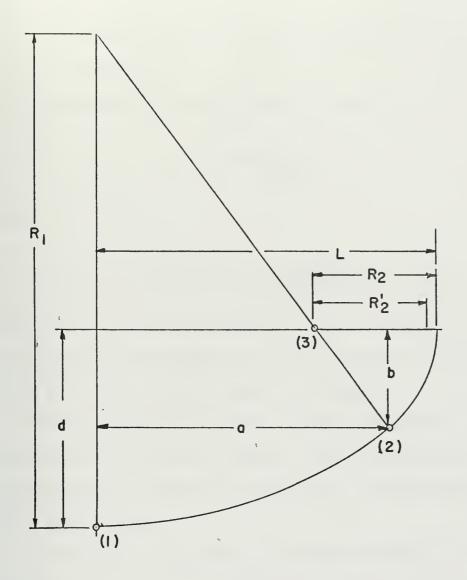

FIGURE 23
Fitting of circular arcs

The largest radius,  $R_1$ , is chosen to give the desired effect of the original sketch. A curve is then drawn from point (1) to point (2), where (2) is an approximate point of the desired curvature change. Point (2) defines a and b for any given distance d. The center of  $R_2$  becomes point (3).

From geometry,  $R_2$  and  $R'_2$  can be defined as

$$R_2 = \sqrt{1 - (a/R_1)^2}$$
 (B3)

and

$$R'_2 = L - a \neq \frac{ab}{\sqrt{R_1^2 - a^2}}$$
 (B4)

Point (2) may be iterated until  $R_2 = R'_2$ . The centers of  $R_1$  and  $R_2$  will then be on the same radius at their tangent point and the curve will fall within the axial length L and height d.

The same procedure as described above was extended to surfaces of more than two circular arc segments, such as surface E, of Fig. 19, by locating the arc centers E-1, E-2, and E-3. Surface F was constructed in a similar manner.

With areas A<sub>1</sub> and A<sub>2</sub> known, a linear distribution of flow area from station (1) to station (2) was chosen. Circles of the diameter which gave the desired area at a given meridional station were then constructed along an approximate mean streamline as shown by the example circles on Fig. 22. Surface B was then sketched in, tangent to the area circles, and fitted with circular arcs as described above. The flow channel was then checked for uniformly increasing area as a function of length, and adjusted to prevent any convergence in the flow area.

### APPENDIX C

#### COMPUTER PROGRAM OMEGA

Program "Omega" is a modification of program "Diffuser" used by Beck [6]. The program is written in Fortran IV for the IBM 360-67 digital computer. The program was established to compute the values of flow rate, Re,  $\Omega$ ,  $\Omega$   $c_f$  and  $\eta_p$  by the methods described in the main text. Table C1 is a listing of the program.

# Cl. Assembly of Input Data

The field specifications for the input data are shown in Fig. 24. Card one of the data deck is a 72 space "Hollerith" statement for data identification. The content of this card is printed immediately below the output title. Card two is a two digit I-format number indicating the number of data points in the deck. Card three is the input of inlet and exit diameters and the value of  $\Omega$ . Cards four and five contain the data recorded for one data point and must be repeated for each point. No other cards need be repeated.

All floating point numbers may be placed anywhere in their field.

I-format numbers must be right justified.

The definitions of the program input variables are given below.

| Fortran<br>Symbol | <u>Definition</u>                  | Format |
|-------------------|------------------------------------|--------|
| NUM               | Number of sets of data points      | I 2    |
| DO1               | Diameter of outer wall station one | F 10.0 |
| DII               | Diameter of inner wall station one | F 10.0 |
| D02               | Diameter of outer wall station two | F 10.0 |

| Fortran |  |        |
|---------|--|--------|
| Symbol  | Definition   | Format |
| DO2     | Diameter of outer wall, station two                | F 10.0 |
| DI2     | Diameter of inner wall, station two                | F 10.0 |
| OMEGA   | Value of shape parameter                           | F 10.0 |
| IRUN    | Number of run                                      | I 3    |
| МО      | Month  | I 3    |
| IDAY    | Day  | I 3    |
| PATM    | Atmospheric pressure                               | F 10.0 |
| PINOZ   | Static pressure upstream of nozzle                 | F 10.0 |
| DPNOZ   | Pressure differential across nozzle                | F 10.0 |
| TNOZ    | Total temperature upstream of nozzle               | F 10.0 |
| TEMP    | Temperature read at barometer                      | F 10.0 |
| P1      | Static pressure at station one                     | F 10.0 |
| Q1      | Dynamic head at station one                        | F 10.0 |
| TT1     | Total temperature measured upstream of station one | F 10.0 |
| TRM     | Ambient room temperature at exit                   | F 10.0 |

# C2. Output

The program output is in three sections. The first section is a printout of data as read from the input cards as a check. The second section is the calculation of flow rate which is divided into input values converted by the program to dimensionally correct units, and output of flow rates computed by the program. The third section is also divided into input values converted by the program and output values of interest in evaluation of diffuser performance.

Table C2 is a sample output of the program.

| CARD                         |                     |     |       |            |     |       |       |     |          |       |       |      |       |

## APPENDIX D

REDUCTION OF DATA FROM SOVRAN AND KLOMP, REFERENCE 2 Data of Ref. 2 were reduced by a Fortran IV program to a form useable for this study. Table Dl is a listing of the program. The diffuser description of Ref. 2 was the same as in Fig. 10.

The definition of the input variables are

| Fortran Symbol | Description  |
|----------------|--|
| ALFAH          | The divergence angle, $\boldsymbol{\alpha}_{\!H},$ of the inner wall |
| ALFAT          | The divergence angle, $\boldsymbol{\alpha}_{T},$ of the outer wall   |
| DIMLL          | The dimensionless length, $\overline{L}/\Delta R$ .                  |
| ARATIO         | Area ratio, A <sub>2</sub> /A <sub>1</sub>                           |
| RRATIO         | Radius ratio, $R_{\rm H1}/R_{\rm T1}$                                |
| RT1            | Radius of outer wall, station one                                    |
| CPR            | Coefficient of pressure recovery                                     |

The axial length was computed from the geometry and a numerical integration was made to obtain  $\Omega$ . The ideal pressure recovery coefficient was computed from the area ratio and used to compute  $\Omega \ \mathbf{c_f}.$ The results are contained in Table D2, where

| Fortran Symbol | Description  |
|----------------|--|
| OMEGA          | The shape parameter, $\Omega$                      |
| CFBAR          | Average local coefficient of friction, $\bar{c}_f$ |
| DIMLL          | The dimensionless length, $\overline{L}/\Delta R$  |
| OCF            | The product, $\Omega c_f$                          |

. ABSTRACT

This study presents the derivation of a diffuser design parameter, which takes into account losses due to the geometry of the diffuser.

A criterion for design of annular diffusers, using the design parameter to predict losses, is developed from reference data and model tests.

A curved wall annular diffuser was designed and tested to verify the predictions of the design criterion for an arbitrary diffuser.
